## INTRODUCTION

**A** CHECK LIST of North American Amphibians and Reptiles has long been wished for by all students of American Herpetology. This list has been prepared generally upon the lines of the American Ornithologists' Union Check List of Birds, and following that example, it has included the species and subspecies which the authors deem valid<sup>1</sup> and of certain occurrence in North America, north of the Rio Grande, and in Lower California, Mexico. Miller's List of North American Land Mammals (Bull. U. S. Nat. Mus., No. 79, 1912) has also been a valued guide.

This volume is the result of lists begun some years ago independently by both authors. The arrangement is on the following system: The higher groups and genera are in systematic sequence, the species are in alphabetic order. No attempt is made to give synonyms. Species not listed are believed to be invalid. The citation of original appearance of names is given for all except such (e. g., family names) as are formed automatically. Following the citation of the original description of each species comes the place of first appearance of the name in its present combination — accurate in so far as we have been able to determine. References are added to Cope's North American Batrachia and to his Crocodilians, Lizards, and Snakes of North America. Both are frequently erratic and inaccurate, but large and excellent portions of both works are to a great extent from the pen of S. F. Baird, as painstaking an investigator as this country has produced. These monographs are in

<sup>1</sup> By this statement it is not meant that the authors in all cases have verified the status of a number of more recently established forms by critical study. The judgment of reliable workers has been accepted where no special reason appeared to contraindicate the validity of the form. As for the admission of subspecies — or rather trinomial designation — for certain forms no special attempt has been made at consistency, the authors on principle leaning towards binominals in all cases where the need of trinominals has not been clearly established.

widespread use, and constitute the most recent attempts toward complete lists. In the case of the difficult genus *Thamnophis* references are given to Ruthven's excellent review. Common names for reptiles and amphibians are in great confusion, and are often of generic rather than of specific application. No attempt is made to recognize any except those which are in well-established usage. The host which have been recently coined by various writers are frequently inapt and almost surely unlikely to survive. It is entirely possible that some vernacular names really often used have escaped our notice, since many are in restricted local use. The type localities are as nearly exact as it is possible to determine. This cannot be said regarding the ranges. Many are obviously faulty, but a sincere attempt has been made to collect records of authentic captures; however, with a literature so extensive and so scattered, records have almost surely been overlooked. In many cases, our knowledge does not warrant drawing hard and fast lines delimiting a form's occurrence, and we often state ranges in purposely general terms. There still is opportunity for valuable field work to determine the precise distribution of many of our most common species. An example is the recent discovery that *Virginia valeriae* is far from rare in parts of New Jersey.

Our hearty thanks are due to many for information and advice, especially to Samuel Henshaw, John Van Denburgh, and Alex. G. Ruthven.

G. K. Noble has assisted considerably in verifying references and searching literature, and for this assistance he has our grateful remembrance.

was a composite species, part of the wording which Linné intended to use in characterizing the black-snake and the hog-nose snake having been combined under *constrictor*. Thus the scale counts 130-40 refer to the hog-nose, the first words "*Habitat in Canada. Kalm,*" refer to the black. Then we read "*Maxillae apertae sinu triguet,*" obviously the hog-nose again. Lastly comes an abbreviated extract of Kalm's account of the black snakes' habits "*Adonitur homines circum pedes sese convolvens, sed innocuus.*" Consequently, *Coluber constrictor* of 1758 being a composite species, Linné, in 1766, exercised his prerogative as first reviser to correct this error. So that in the twelfth edition (p. 385) we find the black snake correctly diagnosed, using much of the same wording as was used in 1758, with the name *constrictor* applied; while on p. 373 we find the hog-nose renamed — *contortrix* — and assigned to the genus *Boa*. The description fits the hog-nose snake accurately, again part of the early diagnosis being repeated and reference is also made to Catesby's plate figuring this species. This renders the name *contortrix* untenable for the Copperhead.
